Instruction Graph Grammar

Andrew Benson

```
Program
                := \mathbf{P}(vs, n)
                                                  programs
                      S(v)
Vertices
                                                  singleton
                ::=
                      v::vs
                                                  cons
                ::= \mathbf{V}(n,c)
  Vertex
                                                  vertex
                := do a then n
 Content
                                                  single action
                      do a until cnd then n
                                                  open loop action
                      if cnd then n else n
                                                  conditional
                      goto n
                                                  goto
                                                  termination
                      end
```

We let $n \in \mathbb{Z}$, the integers.

We let $a \in \mathtt{Actions}$, a sort describing classes of actions, like movement, that a robot might be able to perform. A grammar defining $\mathtt{Actions}$ is assumed.

We let $cnd \in \texttt{Conditions}$, a sort describing classes of conditions, like whether an object is some distance ahead, that a robot might be able to detect. A grammar defining <code>Conditions</code> is assumed.
